摘要

本報告是流浮山自動氣象站在 1986 - 1997 期間的氣候摘要。除列出標準氣候圖表外，亦將流浮山的紀錄與橫瀾島的風紀錄及天文台的氣溫紀錄作出比較。

Abstract

This note gives a climatological summary for Lau Fau Shan Automatic Weather Station during 1986-1997. In addition to standard climatological tables and diagrams, comparisons of wind with Waglan Island and temperature with Hong Kong Observatory are also made.

1. INTRODUCTION

Automatic weather stations were set up in Hong Kong to meet increasing demands for regional meteorological data for engineering projects in areas under development and to improve weather services. There are 26 such stations in operation at present. Lau Fau Shan Automatic Weather Station is one of these stations with a history of more than 13 years. This note is to give a climatological summary for this station.

2. HISTORY OF THE STATION

Lau Fau Shan Automatic Weather Station ($22^{\circ}28'14''$ N, $113^{\circ}58'52''$ E) has been in operation since 16 September 1985. It is situated at Lau Fau Shan Police Station and is adjacent to Hau Hoi Wan about 5 km northwest of Yuen Long town centre. Its location is shown in Figure 1 and 2.

The high hills around the station are :

Kai Kung Leng	(572 m)	10 km to E
Castle Peak	(583 m)	9 km to SSW
Hill east of Tuen Mun	(507 m)	7 km to S

3. DATA

The data used in this note are hourly records measured at Lau Fau Shan Automatic Weather Station between January 1986 and December 1997. A total of 105 192 observations was loaded into the Oracle database of the Hong Kong Observatory and analyzed using SQL (Structured Query Language). It should be noted that there are periods of incomplete data due to equipment or transmission failure.

4. INSTRUMENTS AND METHODS OF OBSERVATION

At automatic weather stations, measurements of wind, dry-bulb temperature, dew point, relative humidity, atmospheric pressure and rainfall are recorded by automatic instruments and data are transmitted to the Hong Kong Observatory at one-minute intervals via telephone circuits. Figures 3(a) and (b) show the instruments viewed from different directions. The following paragraphs describe the instruments and methods of observation used in Lau Fau Shan during the years 1986-1997.

(a) Atmospheric pressure

Atmospheric pressure was measured with a Setra Systems digital barometer, model 361B.

Height above floor = 1.5 m

Height above mean sea-level = 35.5 m

(b) Air temperature, dew point and relative humidity

Dry-bulb temperature and dew point were measured with a Climatronics temperature and dew-point sensor with its sensing elements placed in a Stevenson screen box. Values of relative humidity were calculated from the dry-bulb temperature and dew point. The measurement of dew point has ceased since June 1995.

Daily maximum and minimum temperatures were extracted from 1-minute data in each day.

(c) Wind

Winds were measured with a Mark V cup and vane anemometer with its head 49.7 m above mean sea-level. Hourly mean wind was computed from the 1-minute data in the hour (Yeung et al 1987).

(d) Rainfall

Rainfall was recorded with a Casella tipping bucket rain-gauge with a step size of 0.5 mm.

5. ANALYSIS

(a) Climatological summary

Monthly values of meteorological elements are summarized in Table 1. Readers are reminded that data are subject to loss because of equipment or transmission failure. The effect on rainfall is significant due to missing records during some major rainstorms particularly in July 1994 and October 1995. In such cases, monthly rainfall totals were adjusted using monthly rainfall distribution maps.

(b) Monthly and annual wind roses

The total number of occurrences of concurrent wind speed and direction is computed for each month. Wind directions are grouped into ranges of 30° and wind speeds in m/s into categories as follows: 0.1-3.2, 3.3-8.2, 8.3-14.2 and >14.2 . The percentage frequencies are shown in Table 2 and are plotted in the form of wind roses in Figures 4-6.

It can be seen that the most frequent and prevailing wind direction is east-northeast for September-April and southeast for May-August (see Table 1).

(c) Diurnal variation of wind

Hourly vector mean winds are computed for each month. These are shown in Table 3 and plotted in Figures 7-8. The study of the sea-land breeze system in Hong Kong (Zhang and Zhang 1997) indicates that the land breeze near Lau Fau Shan is generally northeasterly while the sea breeze is westerly in winter and southwesterly in summer. Dominated by this effect, winds back in the afternoon and maximum wind speeds occur in the morning from September to February while winds veer in the afternoon and maximum wind speeds occur in the evening from March to August. It should be noted that in August and September, winds fluctuate considerably in direction under light wind conditions.

(d) Hourly means of meteorological elements

Hourly means in each month for the following elements are shown in Tables 4-7 and are plotted in Figures 9-12.

- (i) mean sea-level pressure
- (ii) air temperature
- (iii) dew point
- (iv) relative humidity

(e) Gust factor

Gust factor is defined as the ratio of hourly instantaneous maximum gust to hourly mean wind. Using the regression equation of gust(G) on hourly mean wind(M), gust factor(GF) can be obtained.

If the regression equation is written as

$$G = a M + b$$

then

$$GF = a + b/M$$

Regression equations for winds in different quadrants and their corresponding gust factors are shown below :

$$G = 1.46 M + 1.69 , \quad r=0.90 \text{ (direction between } 050^\circ \text{ and } 130^\circ, \text{ east)}$$

$$G = 1.44 M + 1.96 , \quad r=0.92 \text{ (direction between } 140^\circ \text{ and } 220^\circ, \text{ south)}$$

$$G = 1.06 M + 2.49 , \quad r=0.86 \text{ (direction between } 230^\circ \text{ and } 310^\circ, \text{ west)}$$

$$G = 1.28 M + 2.24 , \quad r=0.90 \text{ (direction between } 320^\circ \text{ and } 040^\circ, \text{ north)}$$

where r is the correlation coefficient.

Hourly Mean Wind (m/s)	Gust factor			
	East	South	West	North
5	1.80	1.83	1.56	1.73
10	1.63	1.64	1.31	1.50
15	1.57	1.57	1.23	1.43
20	1.54	1.54	1.18	1.39
25	1.53	1.52	1.16	1.37

(f) Extreme values of temperature, rainfall and gust

The top 20 extreme values of maximum and minimum temperatures, maximum gust and maximum hourly, daily and monthly rainfall are listed in Table 8. The extreme values recorded at the Hong Kong Observatory during the same period are also given on the last line for comparison.

Extreme maximum temperatures were due to subsidence ahead of tropical cyclones or prolonged fine weather brought about by ridges. Extreme minimum temperatures were due to cold surges in winter times.

The heaviest rainfall at Lau Fau Shan, as characteristic of Hong Kong, was brought by tropical cyclones and monsoon troughs.

The occurrences of maximum gusts were mostly recorded during the passage of tropical cyclones. They were Faye (July 1992), Koryn (June 1993), Becky (September 1993), Caitlin (August 1994), Helen and Kent (August 1995) and Victor (August 1997). The exceptions are the

case on 6 July 1992 (Rank 9) when a strong southwest monsoon affected the coastal areas and the case on 17 May 1994 (Rank 13) when a northeast monsoon affected the territory.

(g) Comparison of wind with Waglan Island

Differences in wind direction between Lau Fau Shan and Waglan Island, grouped by four quadrants (as in (e) above), are measured with the angle veering or backing from the prevailing wind direction recorded at Waglan Island. These differences are shown in Figure 13. The distributions are single-peak and bell-shaped. Winds at Lau Fau Shan most often veer 30 degrees from the northerlies at Waglan but back 10, 30 and 40 degrees from the easterlies, southerlies and westerlies at Waglan respectively.

Regression equations of hourly wind speeds at Lau Fau Shan (LFS) against those at Waglan Island (WGL) in different quadrants with the speed at Waglan Island exceeding 5 m/s are shown below:

East	:	$VLFS = 0.24 VWGL + 1.41$	$(r = 0.43)$
South	:	$VLFS = 0.42 VWGL + 1.21$	$(r = 0.48)$
West	:	$VLFS = 0.60 VWGL + 0.15$	$(r = 0.54)$
North	:	$VLFS = 0.35 VWGL + 1.32$	$(r = 0.55)$

The linear relationships can only be regarded as fair, as reflected by the small values of correlation coefficients. The wind speed of Lau Fau Shan is about 35% of that at Waglan Island with easterlies, 45% with northerlies and 60 % from other wind directions.

(h) Comparison of temperature with Hong Kong Observatory

Regression equations of daily maximum, minimum and mean temperatures at Lau Fau Shan against those at the Observatory (HKO) are shown below:

daily maximum temperature	:	$TLFS = 1.02 THKO + 0.18$	$(r = 0.96)$
daily minimum temperature	:	$TLFS = 1.08 THKO - 3.04$	$(r = 0.98)$
daily mean temperature	:	$TLFS = 1.06 THKO - 1.90$	$(r = 0.99)$

Excellent linear relationships can be seen in the scatter diagrams with associated regression lines shown in Figure 14.

Generally, the daily maximum temperature is about 1 °C higher than that of the Observatory in summer while the daily minimum temperature is about 2 °C lower in winter. Daily mean temperature is almost the same in summer and 1 °C lower in winter at Lau Fau Shan.

ACKNOWLEDGEMENT

The authors would like to thank Mr. W.K. Kwan for his valuable comments on reviewing this note.
